Facts

- Type 2 diabetes is associated with a high morbidity and mortality
- Tackling glucose only was not successful in reducing MACE and mortality
- Treatment induced adverse events (weight gain and hypoglycemia) were thought to wipe off benefits of glycemic control

Aim of Diabetes management

Anti-hyperglycaemic in the last 90 years

Cardiovascular outcome trials

After years of frustrations...

Macrovascular risk reduction (=MACE)

SGLT-2 inhibitors

CV, cardiovascular; HHF, hospitalisation from heart failure; MACE, major adverse cardiovascular events; MI, myocardial infarction; SGLT-2, sodium–glucose co-transporter-2

1. Zinman B et al. *N Engl J Med* 2015;373:2117–2128; 2. Neal B et al. *N Engl J Med* 2017;377:644–657; 3. Wiviott SD et al. *N Engl J Med* 2018;doi: 10.1056/NEJMoa1812389 [Epub ahead of print]

MACE in GLP1-RA

CV death, non-fatal myocardial infarction, or non-fatal stroke

Patients at risk

Liraglutide	4668	4593	4496	4400	4280	4172	4072	3982	1562	424
Placebo	4672	4588	4473	4352	4237	4123	4010	3914	1543	407

The primary composite outcome in the time-to-event analysis was the first occurrence of death from cardiovascular causes, non-fatal myocardial infarction, or non-fatal stroke. The cumulative incidences were estimated with the use of the Kaplan-Meier method, and the hazard ratios with the use of the Cox proportional-hazard regression model. The data analyses are truncated at 54 months, because less than 10% of the patients had an observation time beyond 54 months.

CI: confidence interval; CV: cardiovascular; HR: hazard ratio.

So ...what are the mechanisms?

Potential mechanisms of cardiovascular benefits of glucagon-like peptide-1 receptor agonists

BP, blood pressure; GLP-1, glucagon-like peptide-1; LDL, low-density lipoprotein

Cardiovascular Actions and Clinical Outcomes With Glucagon-Like Peptide-1 Receptor Agonists and Dipeptidyl Peptidase-4 Inhibitors

ABSTRACT: Potentiation of glucagon-like peptide-1 (GLP-1) action through selective GLP-1 receptor (GLP-1R) agonism or by prevention of enzymatic degradation by inhibition of dipeptidyl peptidase-4 (DPP-4) promotes glycemic reduction for the treatment of type 2 diabetes mellitus by glucose-dependent control of insulin and glucagon secretion. GLP-1R agonists also decelerate gastric emptying, reduce body weight by reduction of food intake and lower circulating lipoproteins, inflammation,

**NIAD
before
Insulin**

Use principles in Figure 1

TO AVOID
CLINICAL INERTIA
REASSESS AND
MODIFY TREATMENT
REGULARLY
(3–6 MONTHS)

Use metformin unless contraindicated or not tolerated

If not at HbA_{1c} target:

- Continue metformin unless contraindicated (remember to adjust dose/stop metformin with declining eGFR)
- Add SGLT2i or GLP-1 RA with proven cardiovascular benefit¹ (See below)

If at HbA_{1c} target:

- If already on dual therapy, or multiple glucose-lowering therapies and not on an SGLT2i or GLP-1 RA, consider switching to one of these agents with proven cardiovascular benefit¹ (See below)

OR reconsider/lower individualised target and introduce SGLT2i or GLP-1 RA

OR reassess HbA_{1c} at 3 month intervals and add SGLT2i or GLP-1 RA if HbA_{1c} goes above target

Take home message

OLD view

MAIN AIM

Early and strict control of
HbA1c (...does not matter
HOW, the lower the better)

BUT

No EVIDENCE for a better
OUTCOME

„GLUCO-CENTRIC“

NEW

Improvement of CV, renal outcome,
reduced mortality!... Better life
expectancy

So far only a few substrates could
show that

„Outcome-oriented“

It does not matter
HOW LOW WE GO

But it matters
HOW WE GO LOW

Change of paradigm needed

**TREAT THE PATIENT
NOT HIS SUGAR
REDUCE THE CV RISK
NOT ONLY THE HBA1C**
